25

26 Abstract

27 Objective

28 To evaluate the accuracy of 35-37 weeks' ultrasound for fetal growth restriction (FGR)  
29 detection and the impact of 30<sup>th</sup>-33<sup>rd</sup> weeks vs 35<sup>th</sup>-37<sup>th</sup> weeks ultrasound on perinatal  
30 outcomes.

31 Design

32 A prospective randomized trial

33 Setting

34 Tertiary referral hospital in Portugal.

35 Population

36 Low risk pregnant women

37 Methods

38 We enrolled 1061 women: 513 in the control group (ultrasound at 30<sup>th</sup>-33<sup>rd</sup> weeks) and  
39 548 in the study group (with an additional ultrasound at 35<sup>th</sup>-37<sup>th</sup> weeks). FGR was  
40 defined as an estimated fetal weight (EFW) below 10<sup>th</sup> percentile. We calculated the  
41 overall accuracy of the 35-37 weeks' ultrasound and compared perinatal outcomes  
42 between both groups.

43 Main outcome measure

44 Detection of late FGR

45 Results

46 The ultrasound at 35-37 weeks had an overall accuracy of FGR screening of 94%.  
47 Spearman's correlation coefficient between EFW and birthweight centile was higher for  
48 at 35-37 weeks' ultrasound ( $\rho = 0.75$ ) compared with 30-33 weeks' ultrasound ( $\rho =$   
49  $0.44$ ). The study group had a lower rate of operative vaginal deliveries (24.4% vs  
50 39.3%,  $p = 0.005$ ) and cesarean deliveries for nonreassuring fetal status (16.8% vs

51 38.8%,  $p < 0.001$ ). For FGR prediction, the area under the receiver-operating  
52 characteristics curve of EFW centile at 35-37 weeks' ultrasound was 0.90 (95% CI,  
53 0.86-0.95).

#### 54 Conclusions

55 A later ultrasound (35-37 weeks) had a higher correlation between EFW and  
56 birthweight centiles and was associated with a lower rate of cesarean and operative  
57 deliveries for nonreassuring fetal status compared to an earlier ultrasound, which  
58 reinforces that antenatal identification of FGR allows close monitoring and appropriate  
59 management.

70 ultrasonography, estimated fetal weight, adverse perinatal outcome, cesarean deliveries,  
71 nonreassuring fetal status

72

#### 73 Tweetable abstract

74 35-37 weeks scan was associated with less cesarean deliveries for nonreassuring fetal  
75 status than 30-33 weeks ultrasound.

## 76 Introduction

77 Sonographic estimation of fetal weight (EFW) during third trimester in low-risk  
78 pregnancy is considered the most effective method for diagnosis of fetal growth  
79 restriction (FGR).<sup>1</sup> However, there is no consensus on the need for a routine third  
80 trimester ultrasound and the best gestational age to perform it. Evidence has not yet  
81 provided advantages on perinatal outcomes.<sup>2</sup> The main argument against a routine third  
82 trimester ultrasound is the possibility of overdiagnosis and unnecessary obstetric  
83 intervention for FGR since a significant proportion of these fetuses are constitutively  
84 small for gestational age (SGA). On the other hand, undiagnosed late FGR constitutes a  
85 significant proportion of term stillbirths<sup>3,4</sup> and is associated with higher risk of adverse  
86 neonatal outcomes when compared to FGR diagnosed during pregnancy.<sup>5,6</sup> Despite this,  
87 it is routinely used in many countries during early third trimester, a strategy that has  
88 been endorsed by the World Health Organization (WHO).<sup>7</sup>

89 In accordance with recent guidelines from The International Society of Ultrasound in  
90 Obstetrics and Gynecology (ISUOG), screening for FGR is an essential component of  
91 antenatal care, and fetal ultrasound plays a key role in assessment of this condition.<sup>8</sup> It is  
92 important to differentiate between the concept of fetal size at a given time point and  
93 fetal growth, the latter being a dynamic process, which requires at least two scans  
94 separated in time. In Portugal, according to local guidelines of Direcção Geral de Saúde  
95 (DGS) from 2015, FGR screening in low risk pregnancies is performed with an  
96 ultrasound for EFW at 30<sup>th</sup>-33<sup>rd</sup> weeks.<sup>9</sup> Nonetheless, data from ROUTE study, that was  
97 a randomized trial, showed that FGR detection rate was superior at 36 vs 32 weeks'  
98 gestation.<sup>10</sup>

99 The aim of this study was to evaluate the accuracy of 35<sup>th</sup>-37<sup>th</sup> weeks' ultrasound for  
100 FGR detection and the impact on perinatal outcomes.

## 101 Methods

102

### 103 Patient recruitment and outcomes

104 A prospective randomized trial was conducted to compare the accuracy of ultrasound  
105 screening for late FGR between 30<sup>th</sup>-33<sup>rd</sup> weeks and 35<sup>th</sup>-37<sup>th</sup> weeks. The study was  
106 approved by the Lisbon Academic Medical Center Ethics Committee (reference number  
107 387/13). This work was supported by a Research Grant from Fundação para a Ciência e  
108 Tecnologia (FCT) -SFRH/SINTD/92997/2013. The funder was not involved in the  
109 study design, collection, analysis, data interpretation nor in the writing of this report.

110 The population included in this study corresponded to low risk pregnant women  
111 referred by the Primary Care units to Hospital Universitário de Santa Maria, Centro  
112 Hospitalar Lisboa Norte, in accordance with local guidelines.

113 According to national guidelines, routine ultrasound scans were performed at 11 + 0 to  
114 13 + 6 weeks' gestation for pregnancy dating, based on crown rump length; screening  
115 for congenital anomalies was performed at 20 + 0 to 22 + 6 weeks' gestation and  
116 screening of abnormal fetal growth at 30 + 0 to 32 + 6 weeks' gestation.

117 After routine third-trimester scanning, women meeting the following inclusion criteria  
118 were eligible to participate in the study: 1) viable singleton non-anomalous fetus; 2)  
119 pregnancy dating by ultrasound performed before 13 + 6 weeks; 3) maternal age at  
120 recruitment  $\geq$  18 years; 4) absence of medical history of diabetes, autoimmune or renal  
121 diseases, hypertension, FGR or stillbirth.

122 Patients who agreed to participate in the study, after signing an informed consent, were  
123 randomized into two groups (with and without an additional scan at 35<sup>th</sup>-37<sup>th</sup> weeks).  
124 Randomization was done through computer software and sequences were generated in  
125 blocks of 100 participants to assure balanced distribution within study arms, in a 1:1

126 allocation ratio. Once a patient consented to enter the trial a sealed opaque envelope was  
127 opened, and the patient was then allocated to the study or control group. It was not  
128 possible to blind participants, obstetricians or outcome assessors to the trial groups.

129 Clinical data was collected at time of enrolment such as: maternal age, ethnicity, parity,  
130 height, weight, body mass index at the beginning of pregnancy, education and smoking  
131 habits. Clinical evaluation included measurement of symphysis-fundus distance (SFD).  
132 Obstetric and neonatal outcomes were registered prospectively after delivery by revising  
133 medical records such as: gestational age at delivery, type of labor, type of delivery,  
134 indication for operative vaginal or cesarean delivery, cardiotocographic (CTG) register  
135 characteristics, gender, birthweight, birthweight centile, evidence of meconium staining  
136 of amniotic fluid, Apgar score, admission to neonatal intensive care unit and perinatal  
137 mortality.

138 Primary outcome was to evaluate the accuracy of 35-37 weeks' ultrasound for FGR  
139 detection and compare the correlation of 35-37 weeks' EFW centile with birthweight  
140 centile with the correlation of EFW centile at 30-33 weeks' ultrasound with birthweight  
141 centile. Secondary outcomes were to compare perinatal data between study and control  
142 groups.

143

#### 144 Ultrasound measurements

145 The ultrasound performed for the study group included biometric parameters of the  
146 fetus: biparietal diameter (BPD), head circumference (HC), abdominal circumference  
147 (AC) and femur length (FL). All were obtained at the appropriate levels described  
148 elsewhere, with the fetal structure of interest filling at least 30% of the monitor.<sup>11,12</sup> BDP  
149 and HC were taken from axial images of the fetal brain at the transthalamic plane, with  
150 an angle of insonation as close as possible to 90°. Particularly in late gestation, this

151 section plane is easier to identify and allows more reproducible measurements than does  
152 the transventricular plane.<sup>13</sup> The midline echo (representing the falx cerebri) had to be  
153 broken anteriorly, at a third of its length, by the cavum septum pellucidi. BPD was  
154 measured by outer-to-inner calliper placement at the widest part of the skull. We  
155 adopted outer to inner technique in order to avoid artefacts generated by the distal echo  
156 of the calvarium. AC measurement was taken in a cross-sectional view of the fetal  
157 abdomen as close as possible to circular, at the level of the bifurcation of the main  
158 portal vein into left and right branches and with the stomach visible. Both HC and AC  
159 were measured using the ellipse facility on the outer border of the skull and of the  
160 abdomen, respectively. FL was measured using a longitudinal view of the fetal thigh  
161 closest to the probe and with the femur as close as possible to the horizontal plane.  
162 Measurement was performed with the full length of the bone visualized by including  
163 only the femoral diaphysis length, excluding the hypoechogenic cartilaginous structures  
164 at either end of femur. Based on these four measurements, the computer system  
165 (Astraia®) provided the EFW and respective percentile according to the Hadlock  
166 formula<sup>14</sup> and Yudkin curves.<sup>15</sup> Amniotic fluid was measured by single pocket depth.  
167 Functional evaluation included: Doppler of the umbilical artery (UA), middle cerebral  
168 artery (MCA) and uterine artery (UtA). The respective pulsatility index (PI) and  
169 cerebroplacental ratio (CPR) were registered.

170

171 Definition of FGR and monitoring

172 FGR was defined according to the American College of Obstetricians and  
173 Gynecologists (ACOG) as a fetus with an EFW below the 10<sup>th</sup> percentile and SGA as a  
174 newborn with a birthweight below the 10<sup>th</sup> percentile.<sup>16</sup>

175 For the control group, local guidelines for follow up were followed with serial  
176 evaluation of the SFD at the scheduled appointments at 35, 38, 40 and 41 weeks. If this  
177 distance was less than 31 cm at 35 weeks or less than 34 cm at 38, 40 and 41 weeks, the  
178 clinical suspicion of FGR mandated an ultrasound evaluation as described above. If no  
179 deviation of SFD was found, induction of labor was scheduled after 41 weeks and  
180 delivery route was decided by obstetric criteria.

181 In accordance with our Department's protocol for surveillance of FGR, the management  
182 follow up was as described below:

183 - FGR with EFW < 10<sup>th</sup> centile and normal Doppler - Doppler re-evaluation after one  
184 week of diagnosis and EFW + Doppler after two weeks. If Doppler is normal and the  
185 fetus remains on the same growth curve, ultrasound controls are performed every two  
186 weeks and delivery is scheduled at 39 weeks.

187 - FGR with EFW or AC < 3<sup>rd</sup> centile or EFW < 10<sup>th</sup> centile + UA IP > 95<sup>th</sup> centile:  
188 weekly Doppler and CTG. EFW every two weeks. If normal Doppler in all evaluations,  
189 delivery is scheduled at 37 weeks.

190 - FGR with CPR < 5<sup>th</sup> centile or MCA PI < 5<sup>th</sup> centile; Doppler evaluation three times  
191 per week; CTG every eight hours; EFW every two weeks. If no additional Doppler  
192 anomalies in all evaluations, delivery is scheduled at 37 weeks.

193 - FGR with absent or reversed end diastolic flow in UA are indications for delivery at  
194 the gestational age of the ultrasound evaluation in the study group.

195 For all groups, in case of Doppler anomalies, they were confirmed within 6-12 hours.

196 Delivery route was decided according to obstetric criteria.

197 For both groups, confirmation of antenatal detection of FGR was assessed after the baby  
198 was born, by comparing antenatal EFW centiles of both ultrasounds with birthweight  
199 centiles.

200 Nonreassuring fetal status was defined by the interpretation of continuous CTG, using  
201 the ACOG classification.<sup>17</sup>

202

203 Statistical analysis

204 Normal distributions were assessed using the Kolmogorov-Smirnov test. Data are  
205 presented as mean  $\pm$  standard deviation (SD), median (interquartile range (IQR)) or  
206 number of subjects (%). Statistical analyses were performed using STATA 14.1  
207 (Statacorp, College Station, Texas, US) and R-3.3.2.

208 Chi-square tests or Fisher's exact test and Students t-test or Mann-Whitney U test were  
209 used to compare categorical and continuous variables between groups, respectively.

210 Spearman's correlation coefficient was used to test the correlation between EFW centile  
211 and birthweight centile.

212 According to our retrospective data, the antenatal detection rate of FGR at 30-33 weeks'  
213 ultrasound was 20.5% for low risk pregnancies.<sup>18</sup> Aiming to increase the detection rate  
214 by at least 7% with an ultrasound at 35<sup>th</sup>-37<sup>th</sup> weeks (study group), the investigators  
215 would require a total sample of 1200 women (600 in each group - control with  
216 ultrasound at 30-33 weeks and study with an additional ultrasound at 35-37 weeks),  
217 with 80% power and a significance  $\alpha$  level of 0.05. Analysis was based on originally  
218 assigned groups (intention-to-treat). A secondary per-protocol analysis was performed  
219 by excluding the cases that missed the scheduled ultrasound from the study group and  
220 the cases that were submitted to an additional ultrasound after enrolment from the  
221 control group.

222 For all comparisons, two-sided  $p$  values  $< 0.05$  were considered statistically significant.

223

224 Results

225 Figure 1 shows a flowchart of the participants and the reasons for exclusion in both  
226 groups. Pregnant women were enrolled between July 2015 and May 2019. A total of  
227 1093 pregnant women were randomized to control (n =535) and study (n = 558) groups.  
228 Of these women, 32 (2.9%) were lost to follow up (2 before the scan and 30 during the  
229 scan-to-delivery interval). Baseline characteristics of participants lost to follow-up were  
230 comparable to the 1061 who completed the study, except for a lower maternal age at  
231 randomization in the subset lost to follow up (Table 1). Demographic characteristics did  
232 not differ between control (n =513) and study (n = 548) groups (Table 2). Table 3  
233 summarizes perinatal outcomes. A total of 98 (9.2%) newborns were found to be SGA  
234 (birthweight < 10<sup>th</sup> centile). Within the 52 cases of SGA in the study group, the  
235 ultrasound at 35-37 weeks' gestation detected 26 (50%). Although the rates of operative  
236 vaginal and cesarean deliveries were similar for the two groups, the study group had a  
237 lower rate of operative vaginal deliveries for nonreassuring fetal status (24.4% vs  
238 39.3%,  $p = 0.005$ ) and also a lower rate of cesarean deliveries for nonreassuring fetal  
239 status (16.8% vs 38.8%,  $p < 0.001$ ), (Table 3). No perinatal mortality was registered in  
240 any of the groups.

241 Per protocol, 501 and 510 participants underwent an additional scan at 35 to 37 weeks'  
242 gestation and were included in control group (followed the national recommendation of  
243 third trimester ultrasound at 30-33 weeks), respectively. Forty-seven (8.6%) participants  
244 did not attend the ultrasound that was scheduled for the study group. We tried to contact  
245 these patients by phone to reschedule the scan, but in 30 patients there was no date  
246 available to perform the scan in the gestational age frame defined and 17 patients did  
247 not answer the phone. In the control group, three women performed a scan for low SFD  
248 and all of these were excluded before per protocol analysis. Baseline characteristics  
249 were comparable between groups (Table S1). The rate of SGA was similar between

250 study and control groups [50/501 (10%) vs 45/510 (8.8%),  $p = 0.53$ ]. Similarly to the  
251 intention-to-treat analysis, the study group had a lower rate of operative vaginal  
252 deliveries for nonreassuring fetal status [36/158 (22.8%) vs 52/134 (38.8%),  $p = 0.003$ ]  
253 and also a lower rate of cesarean deliveries for nonreassuring fetal status [16/101  
254 (15.8%) vs 40/103 (38.8%),  $p < 0.001$ ], compared to control group (Table S1). For the  
255 study group, 31 cases had a diagnosis of FGR at the 35-37 weeks' ultrasound.  
256 Comparing this group with the group with EFW  $\geq 10^{\text{th}}$  centile, the median gestational  
257 age at delivery was lower for the FGR group [39 (38-39.6) vs 40.1 (39.1-40.6),  $p$   
258  $< 0.001$ ].

259 Considering only the pregnant women that performed ultrasound at 35-37 weeks'  
260 gestation in the study group ( $n = 501$ ), this exam detected correctly 26 cases of FGR  
261 that had been missed by the standard 30-33 weeks' gestation ultrasound and also  
262 correctly considered appropriate weight for gestational age 446 cases (EFW  $10^{\text{th}}$   
263 centile) that corresponded to newborns with appropriate weight for gestational age at  
264 delivery (birthweight  $10^{\text{th}}$  centile), with overall accuracy, i.e. (true positives + true  
265 negatives)/all observations of 94% (26+446)/501.

266 Spearman's correlation coefficient was higher between the EFW centile at 35-37 weeks'  
267 ultrasound and birthweight centile ( $\rho = 0.75$ ) than the correlation coefficient between  
268 the EFW centile at 30-33 weeks' ultrasound and birthweight centile ( $\rho = 0.44$ ).

269 For prediction of FGR, area under the receiver-operating characteristics (ROC) curve  
270 (AUC) of estimated fetal-weight centile at 35-37 weeks' ultrasound was 0.90 (95% CI,  
271 0.86-0.95) (Figure S1). Table S2 demonstrates the performance of the ultrasound for  
272 FGR detection.

273

274 Discussion

275 Main findings

276 This prospective randomized trial provided evidence that performing a routine third  
277 trimester ultrasound at 35-37 weeks' gestation had an overall accuracy of 94% for FGR  
278 detection and was associated with better perinatal outcomes. If we compare this data  
279 with our previous retrospective study,<sup>18</sup> that included low risk pregnancies with routine  
280 third trimester screening at 30-33 weeks' gestation,<sup>9</sup> this earlier ultrasound had a lower  
281 overall accuracy of 89%.

283 Strengths and limitations

284 Despite our small sample, we have only included low risk pregnancies with no maternal  
285 risk factors, and we followed a specific protocol after diagnosis of FGR at 35-37 weeks'  
286 gestation ultrasound with well-defined follow up scans and timing to schedule delivery.  
287 The lower gestational age at delivery for the group with EFW < 10<sup>th</sup> centile at 35-37  
288 weeks' gestation compared with EFW ≥ 10<sup>th</sup> centile may reflect the different  
289 surveillance and management provided for the first group. Since national guidelines  
290 recommend 30-33 weeks' screening ultrasound, we could not have avoided this scan in  
291 the study group, so we have only included patients that already had an appropriate EFW  
292 at 30-33 weeks. This strategy of serial scanning in the study group may have  
293 contributed to improve detection of FGR and perinatal outcomes.

294 A limitation of our study was slow recruitment, which led us to stop the trial when we  
295 had more than 90% of the planned sample. We consider that this decision does not  
296 affect the conclusions of our trial since we found significant differences of accuracy  
297 between 30-33 weeks' and 35-37 weeks' gestation ultrasounds and also important  
298 clinical and statistical differences in meaningful perinatal outcomes. Recruitment of  
299 patients in only one hospital has contributed to slow recruitment and may hamper

300 generalization of the results but has also allowed us to have a very low rate of loss to  
301 follow up (2.9%).

302

303 Interpretation

304 In our series, the AUC of 90% reinforces that an ultrasound at 35<sup>th</sup>-37<sup>th</sup> weeks' has a  
305 good performance for screening of FGR. Previous studies have already demonstrated  
306 that FGR detection rate was superior at 36 vs 32 weeks' gestation,<sup>10</sup> but without better  
307 perinatal outcomes.<sup>2,10</sup> For one instance, metanalysis have limited contemporary validity  
308 as they have used outdated surrogates of fetal growth or protocols in which FGR  
309 diagnosis elicited no change in management.<sup>2</sup> Furthermore, some studies have included  
310 pregnant women with maternal risk factors diagnosed after randomization which may  
311 have introduced a bias in the evaluation of perinatal outcomes.<sup>10</sup>

312 The higher correlation coefficient between EFW centile at 35-37 weeks' ultrasound and  
313 birthweight centile when compared to 30-33 weeks' ultrasound is in accordance with  
314 other studies that concluded that the closer the delivery occurs to the assessment, the  
315 higher the predictive performance of the scan.<sup>19,20</sup> Furthermore, a later scan during third  
316 trimester may be more appropriate to identify fetuses that only begin to decelerate their  
317 growth after the scan at 30-33 weeks' gestation. One can argue that if we consider  
318 replacing the 30-33 weeks' ultrasound by a later scan, the delay in the diagnosis of FGR  
319 may contribute to adverse perinatal outcomes. Our study was underpowered to detect  
320 events with low prevalence such as perinatal mortality, but others have already  
321 demonstrated that fetal death is higher for FGR in the late term and post term periods  
322 than in the preterm period.<sup>21</sup>

323 Some authors,<sup>22,23</sup> but not all,<sup>24,25</sup> have reported that reduced third trimester growth  
324 velocity is associated with an increased incidence of certain adverse pregnancy

325 outcomes. According to ISUOG guidelines and Delphi consensus, fetal growth analysis  
326 may help in the management of pregnancy.<sup>8,26</sup> An additional ultrasound during the third  
327 trimester has constrains in terms of human and economic resources available to be  
328 feasible. However, we have also to consider the potential reduction of costs that will be  
329 possible by reducing obstetric intervention during delivery. This should be clarified in a  
330 future cost-effective study.

331

### 332 Conclusions

333 To conclude, in a country that recognizes the value of routine third trimester ultrasound  
334 screening of FGR for low risk pregnancies, our data is important to reinforce that a later  
335 ultrasound during the third trimester has a high accuracy for detection of FGR and has a  
336 high correlation between EFW and birthweight centiles. Furthermore, it may also  
337 contribute to diminish adverse perinatal outcomes compared to an earlier ultrasound  
338 during third trimester, which reinforces that antenatal identification of FGR allows close  
339 monitoring and appropriate management, preventing the need of emergent obstetric  
340 intervention during labor and delivery.

352 Disclosure of interests

353 The authors report no conflict of interest

354

355 Author contributions

356 CP had the idea for the study. CP, NC and LMG designed the study. CP, AF, JB, SV,

357 DM, CRC, MC, IM, performed the ultrasounds and recruited patients. CP and JM

358 performed the statistical analysis. CP wrote the first draft of the article. AF, JB, SV,

359 DM, MC, CRC, JM, IM, NC and LMC checked the analysis, revised and co-wrote the

360 article.

361

362 Details of Ethics Approval

363 The study was approved by the Lisbon Academic Medical Center Ethics Committee in

364 November 2013 (reference number 387/13).

365

366 Funding

367 This work was supported by a Research Grant from Fundação para a Ciência e

368 Tecnologia (FCT) -SFRH/SINTD/92997/2013.
