1. Figure S1 to Figure S6
2. Table S2 to Table S3

Figure S1. Estimating V_P , V_S , and olivine content. **a** 70 Ma half-space cooling (HSC) geotherm with mantle potential temperature $T_P = 1350^\circ\text{C}$. **b**, **c** Mineral physics calculations of Voigt average V_P and V_S (red solid lines) and **d** mineral abundance from Perple_X (Connolly, 2009), using the solution models of Stixrude & Lithgow-Bertelloni (2011) and assuming a depleted mid-ocean ridge basalt (MORB) mantle composition (Hacker, 2008). The average velocities for the upper 7 km, NoMelt_SPani7, is indicated by the yellow star. Although the predicted velocity gradients are less steep for both V_P and V_S (and for V_P , opposite in sign), there is fair agreement with the depth averaged NoMelt velocities. Modal estimates yield $\sim 60\%$ olivine. Ol = olivine; Cpx = clinopyroxene; Opx = orthopyroxene; Gt = garnet; Pl = plagioclase

Figure S2. Orthopyroxene texture used in calculations. A generic orthopyroxene texture from the torsion experiments of Hansen et al. (2014). The fabric is extremely weak ($\sim 0.4\%$ V_P anisotropy) and oriented with its [100] crystallographic axis perpendicular to the shear plane, [001] sub-parallel to the shear direction, and [010] perpendicular to shear and in the shear plane.

$$dV_S = 200(V_{SH} - V_{SV}) / (V_{SH} + V_{SV})$$

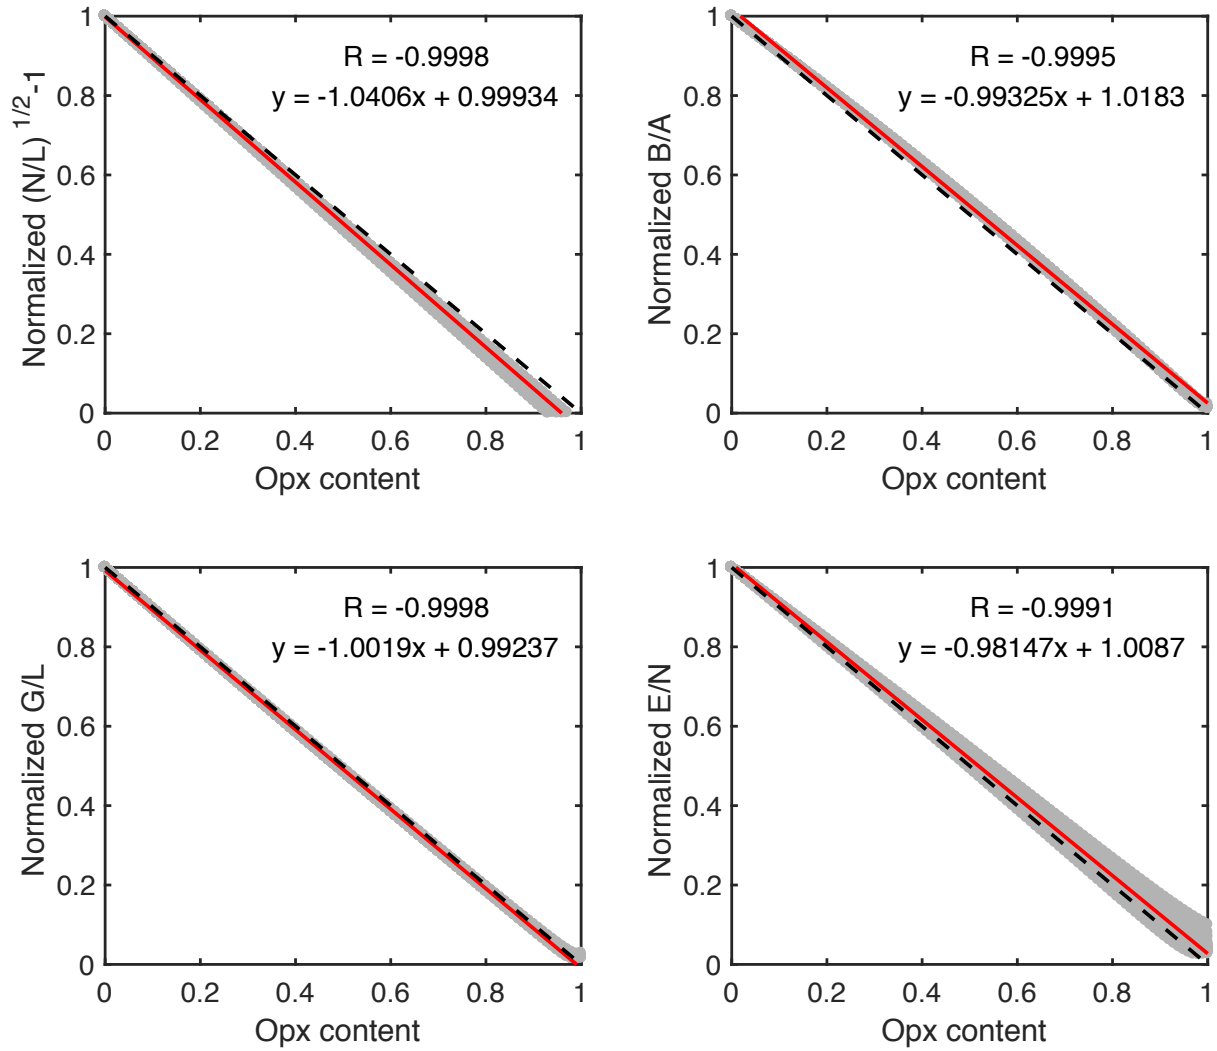

Figure S3. Reduction in anisotropy strength with increasing orthopyroxene content. Using well-developed laboratory olivine samples from Hansen et al. (2014, 2016) with shear strains of $\gamma > 2$, shown in grey, scaling relationships are found between orthopyroxene content and anisotropy strength (using the orthopyroxene fabric in Figure S2; see methods for details). Anisotropy values for each sample are normalized by the pure olivine estimate in order to determine a single scaling relation for all samples. The best fit line that describes anisotropy reduction with increasing orthopyroxene is shown in red, and nearly falls along the -1:1 line dashed in black.

Figure S4. Effect of assumed olivine content on LPO-type comparison. a–c, As in Figure 5 in the main text. Circles show anisotropy averages assuming varying ratios of olivine and pyroxene content, where symbol size scales with the amount of olivine ranging from 60% to 100% in increments of 5%, and color denotes fabric type. Anisotropy strength decreases with decreasing olivine content. The best fitting composition of 75% olivine and 25% is shown in cyan.

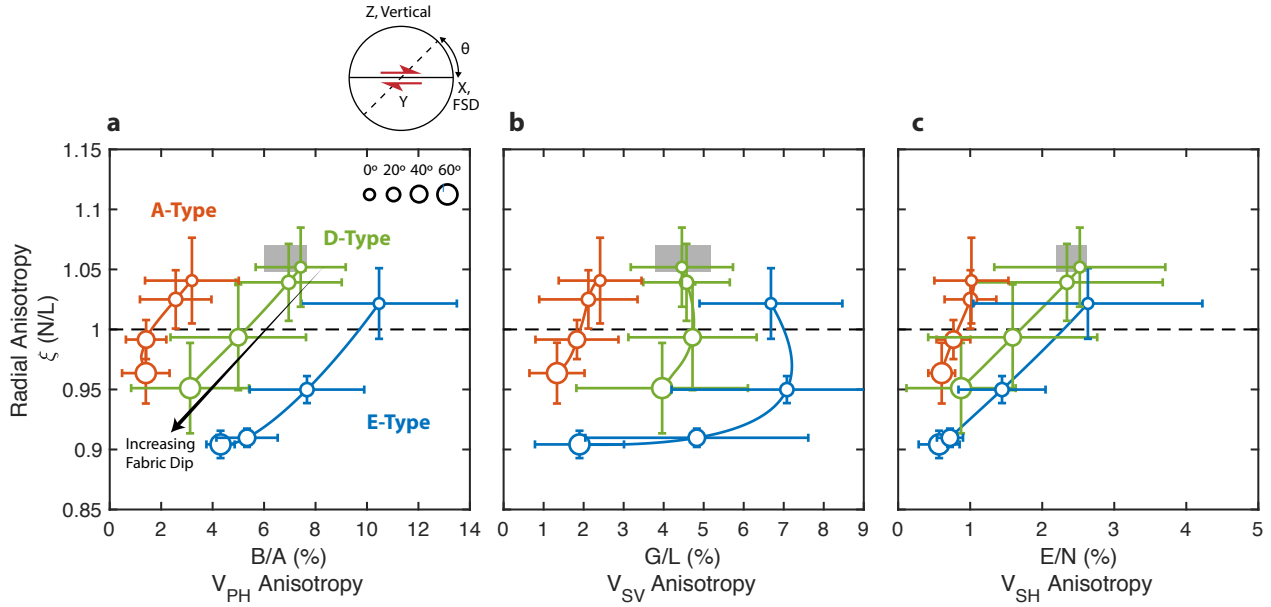

Figure S5. Effect of fabric dip on LPO-type comparison. **a–c**, As in Figure 5 in the main text. Symbols show anisotropy averages and one standard deviation after rotating samples about the Y axis by an angle θ , effectively rotating $[100]$ out of the shear plane. Symbol size scales with introduced fabric dip ranging from 0° to 60° , and color denotes fabric type. A composition of 75% olivine and 25% orthopyroxene is assumed. Radial and azimuthal anisotropy generally decreases with increasing fabric dip. In detail, V_{SV} anisotropy in **b** shows a more complex behavior, in particular for samples with strong azimuthal anisotropy, where an initial slight increase with dip to $20\text{--}40^\circ$ is followed by a nonlinear decrease.

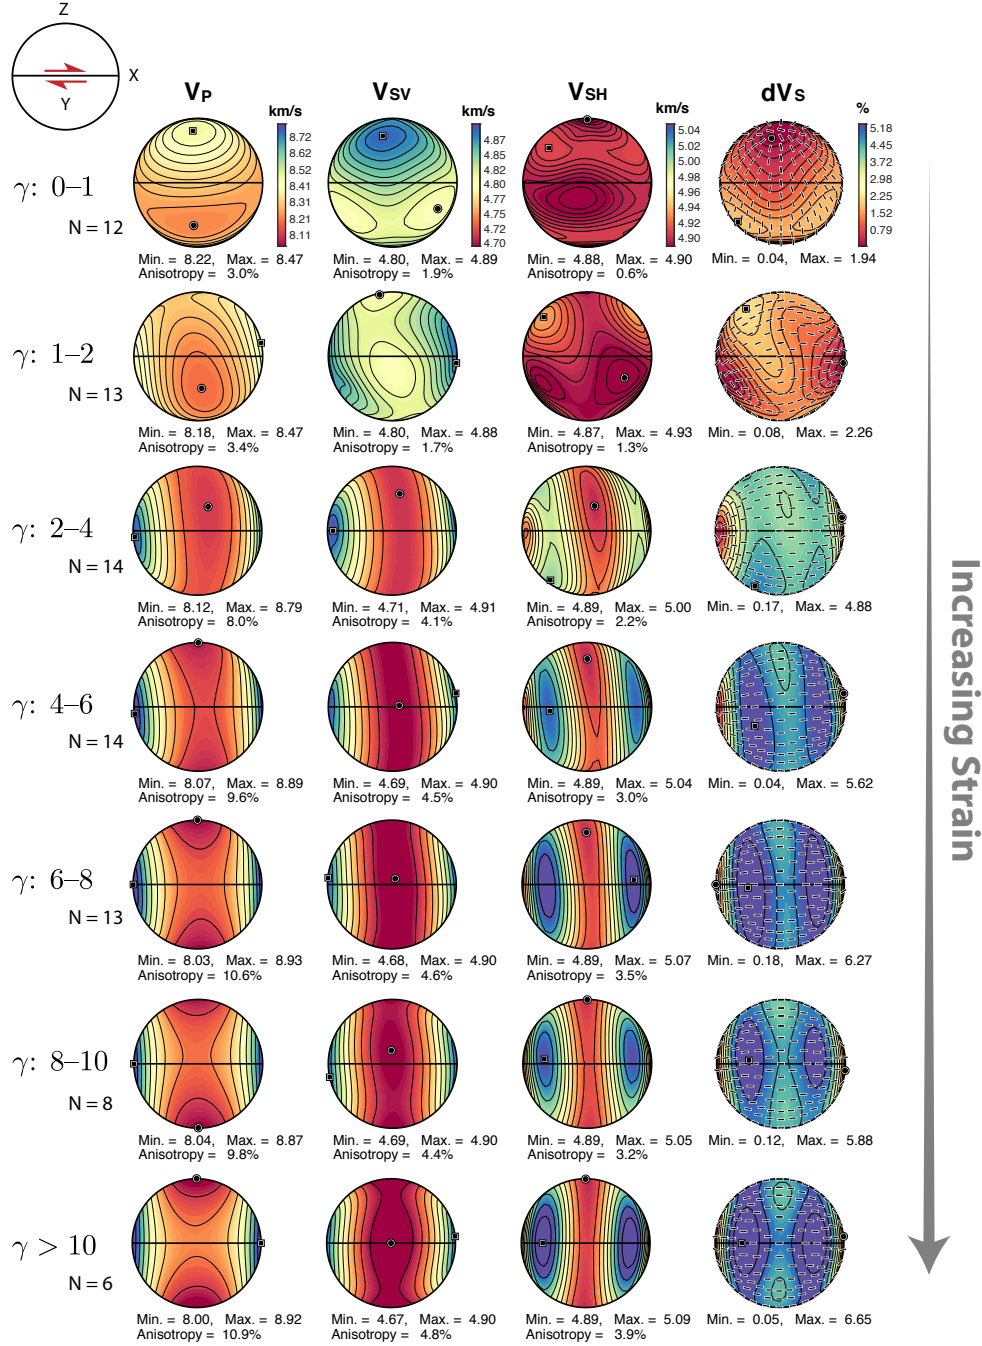

Figure S6. Strain evolution of anisotropy for laboratory samples shown in Figure 3.

(left to right) Columns show V_P , V_{SV} , V_{SH} , and dV_S anisotropy for laboratory samples from Hansen et al. (2014, 2016) grouped and averaged by shear strain for 60% olivine and 40% pyroxene. (top to bottom) Each row represents an average of all samples within the range of γ indicated at the left of each row. Strain increases from top to bottom. A common color scale is used for each column. $dV_S = 200(V_{SH} - V_{SV})/(V_{SH} + V_{SV})$

Table S1. NoMelt_SPani transversely isotropic velocity model with depth relative to sea surface.

Depth (km)	V_{SV} (km/s)	V_{SH} (km/s)	V_{PV} (km/s)	V_{PH} (km/s)	η	ρ (g cm ⁻³)

Table S3. Nominal flow law and grain-size evolution parameters used to calculate the

wattmeter and deformation mechanism maps

Symbol	Description	Value	Units
R	gas constant	8.314	$\text{J mol}^{-1} \text{K}^{-1}$
T	temperature	1523	K
P	pressure	360	MPa
G_0	dry grain growth rate constant	1.5×10^{-5}	$\text{m}^p \text{s}^{-1}$
E_g	activation energy for grain growth	350	kJ mol^{-1}
V_g	activation volume for grain growth	8×10^{-6}	$\text{m}^3 \text{mol}^{-1}$
p	grain growth exponent	3	
χ	fraction of work done by dislocation mechanisms	0.03	
γ	average specific grain boundary energy	1	J m^{-2}
c	geometric constant	3	
n_{GBS}	disGBS stress exponent	2.9	
m_{GBS}	disGBS grain-size exponent	0.7	
A_{GBS}	disGBS prefactor	$10^{4.8}$	$\mu\text{m}^{-0.7} \text{MPa}^{-2.9} \text{s}^{-1}$
E_{GBS}	disGBS activation energy	4.45×10^5	J mol^{-1}
V_{GBS}	disGBS activation volume	1.5×10^{-5}	$\text{m}^3 \text{mol}^{-1}$
n_{DISL}	dislocation creep stress exponent	3.5	
m_{DISL}	dislocation creep grain-size exponent	0	
A_{DISL}	dislocation creep prefactor	1.1×10^5	$\text{MPa}^{-3.5} \text{s}^{-1}$
E_{DISL}	dislocation creep activation energy	5.3×10^5	J mol^{-1}
V_{DISL}	dislocation creep activation volume	1.5×10^{-5}	$\text{m}^3 \text{mol}^{-1}$
n_{DIFF}	diffusion creep stress exponent	1	
m_{DIFF}	diffusion creep grain-size exponent	3	
A_{DIFF}	diffusion creep prefactor	$10^{7.6}$	$\mu\text{m}^{-3} \text{MPa}^{-1} \text{s}^{-1}$
E_{DIFF}	diffusion creep activation energy	3.75×10^5	J mol^{-1}
V_{DIFF}	diffusion creep activation volume	1×10^{-5}	$\text{m}^3 \text{mol}^{-1}$
